Artos
BiSS C Register Access

The BiSS C interface implemented in Artos supports bidirectional communication in register access mode. The readhead is user configurable. Implementation is compliant with BiSS C (also Standard Encoder Profile known as "BP3"), which is used to group linear and rotary encoders. Details on BiSS register access and BP3 can be found on the **BiSS website**.

User implementation: User can implement bidirectional BiSS in their own hardware according to the BiSS documentation provided by iC-Haus. As an alternative it is also possible to use the iC-Haus chip iC-MB4, which translates the high-level commands on the SPI bus into BiSS. The easiest way is to use the interface E201-9B from RLS including the corresponding software.

	0x3A – 0x3E	-	Reserved	U8	-	/
	0x3F	CHKSUM	Checksum (sum of all bytes within this bank)	U8	-	xx

All parameters from EDS banks are read-only.

* Actual value not measured.

** Parameter value depends on actual part number.

Encoder identification bank

Bank	Address	Data Type	Access	Default value	Description
2	0x00 – 0x06	6xU8	R	*	RLS serial number (ASCII characters)
	0x07 – 0x13	U8	R	-	Reserved
	0x14 – 0x27	20xU8	R	*	RLS part number (ASCII characters)
	0x28 – 0x29	U16	R	4	FW major version
	0x2A – 0x2B	U16	R	*	FW minor version
	0x2C – 0x2D	U16	R	*	FW hotfix version
	0x2E – 0x31	U32	R	*	FW build version
	0x32 – 0x35	4xU8	R	*	FW version short hash
	0x36 – 0x3E	U8	R	-	Reserved
	0x3F	U8	R	xx	Checksum (sum of all bytes within this bank)

* Most values of parameters in identification bank depend on actual part number.

Encoder configuration bank

Bank	Address	Data Type	Access	Value in effect	Default value	Min / max	Description
3	0x00 – 0x03	U32	RW	Immediate	0	Rotary: 0...SIP_RES Linear: $0...2^{FI\_LEN}$	Position offset
	0x04 – 0x0B	U8	R	-	/	-	Reserved
	0x0C – 0x0F	U32	RW	Power-on	190	0...240	Velocity filter value
	0x10 – 0x18	U8	R	-	/	-	Reserved
	0x19	U8	RW	Power-on	0	0...1	Counting direction change
	0x1A	S8	RW	Immediate	115	–127...127	LED turn off temp.*
	0x1B	S8	RW	Immediate	110	–127...127	LED turn on temp.*
	0x1C – 0x3D	U8	R	-	/	-	Reserved
	0x3E	U8	RW	After “c” command	0x5A	0...255	Write protect lock
	0x3F	U8	R	-	xx	0...255	Checksum (sum of all bytes within this bank)

* The LED is switched on by default. If the temperature rises to “LED turn off temp.”, the LED is switched off. As soon as the temperature falls below the “LED turn on temp.”, it is switched on again. If “LED turn off temp” and “LED turn on temp” are set to –127, LED is turned off.

Self-calibration bank

Bank	Address	Data Type	Access	Default value	Min / max	Description
4	0x00 – 0x03	U32	R	0	-	Self-calibration status
	0x04 – 0x05	U8	R	0	-	Reserved
	0x06 – 0x07	U16	R	0	-	Ring eccentricity shift from rotation axis centre [µm] This parameter is updated only if self-calibration is successful.
	0x08 – 0x09	U16	R	0	-	Ring eccentricity angle (phase) [deg] This parameter is updated only if self-calibration is successful.
	0x0A – 0x0B	S16	R	0	-	Average readhead radial shift (distance to nominal ride height: Actual RH [µm] = nominal RH – radial shift) [µm] This parameter is updated only if self-calibration is successful.
	0x0C	U8	RW	10	1...40	Calibration timeout [s]
	0x0D – 0x3E	U8	R	/	-	Reserved
	0x3F	U8	R	xx	-	Checksum (sum of all bytes within this bank)

Some of writable parameters values are taken into account immediately after value gets changed by writing to this register. For these registers it is not needed to save configuraton to non-volatile memory if setting will only be needed in current power cycle.

Direct access registers

Address	Data Type	Access	Default value	Description
0x40	U8	RW	0	Bank select
0x41	U8	R	1	EDS bank
0x42 – 0x43	U16	R	*	Profile ID (table B – BP_ID)
0x44 – 0x47	U32	R	*	Serial number (encoded)
0x48	U8	RW	255	Key register
0x49	U8	RW	255	Command register
0x4A – 0x4D	U32	R	0	Encoder detailed status (see chapter "**Encoder operating parameters**")
0x4E – 0x4F	S16	R	**	Sensor temperature in °C
0x50 – 0x53	U8	R	0	Reserved
0x54 – 0x57	S32	R	**	Measured velocity in: • 0.1 rpm for rotary encoders (except FlexAB) • 0.01 rpm for FlexAB • mm/s for linear encoders
0x58 – 0x5B	U32	R	0**	Persistent detailed status
0x5C	U8	R	0**	Parameter access status register – see **table E**
0x5D - 0x73	U8	R	-	Reserved
0x74 – 0x77	U32	R	Same as in Identification bank	Major FW version
0x78 – 0x7D	U8	R	*	Device ID
0x7E – 0x7F	U16	R	0x5253	Manufacturer ID

* Parameter value depends on actual part number.
** Parameter value changes during operation.

* scale length [µm] = 2000 × Number of magnetic poles

Table E (Parameter access status register)

Bit	Description
0	Write access denied
1	Value out of range
2 - 5	Reserved
6	Command fetched and executed
7	Write lock active

Bits are persistent - they get cleared on register read, except “Write lock active”, which can not be cleared.

Bank switching

BiSS registers are grouped into the banks in size of 64 bytes. Each register in each bank can be accessed with the address from 0x00 to 0x3F. Before access to a certain bank, it has to be selected in the Bank select register, which is mapped to address 0x40. For further information on bank switching refer to documentation provided by iC-Haus.

Read access

All registers in Artos memory are readable. Read access also supports sequential reading. It is possible to read up to 64 bytes forward from initialized read address. For detailed description on sequential read access refer to documentation provided by iC-Haus.

Write access

Writable registers in Artos memory are presented in chapter **Memory layout**. All registers can be write-protected if write access is locked by the user, except of Bank select register. Sequential write access is available in all banks. For detailed description on sequential write access refer to documentation provided by iC-Haus.

Encoder operating parameters

Address	Data Type	Access	Description
0x4A – 0x4D	U32	R	Encoder status
0x58 - 0x5B	U32	R	Persistent encoder status
0x4E – 0x4F	S16	R	Sensor temperature in °C
0x54 – 0x57	S32	R	Rotational speed
0x00 – 0x03	U32	R	Self-calibration status (bank 4)

Encoder status

Detailed status bits represent current operational state of the encoder. For more information refer to DRD01 in “BiSS C Communication interface” chapter at **RLS Media center**.

Persistent encoder status

This is similar to “Encoder status”, but with the added functionality that all detailed statuses are accumulated. Any error or warning that appears in Detailed Status during operation of encoder is copied into Persistent detailed status. Even if the value in Detailed Status has very short duration, the past statuses can be read from this Persistent register. It keeps the value as long as the power is present. Clearing is possible either by a power cycle or by writing the command ‘b’ to the Command register.

Sensor temperature

Temperature of the sensor in °C. This value is typically 10 °C to 15 °C higher than ambient. Tolerance of the readout is ±5 °C. Temperature is updated every ~2 seconds and it is valid ~2 seconds after startup.

Measured speed

Encoder rotational speed is measured in 0.1 rpm for solid rings, 0.01 rpm for FlexAB and mm/s for linear and partial arc encoders.

Self-calibration status

See chapter **Self-calibration.**

Artos programming

Position offset (encoder zero position) and register write protection can be programmed to the Artos readhead. Additional to this, the readhead can be self-calibrated or reset to the factory defaults. Values written into registers take effect immediately, with some exceptions - see “value in effect” column in registers description tables.

Command execution

To execute a command use the following sequence:
Write value 0xCD to Key register at address 0x48.
Write command byte to Command register at address 0x49.

Write to the key and command register must be sequential. No other register access should take place in between, otherwise command will not be executed. Any other register access after the correct key is entered, invalidates the key value and the command write procedure has to be repeated.

After each command is fetched by encoder, communication is disabled during command execution.
Communication is enabled only after command has executed which can last up to 100 ms.
During this time encoder will not respond to communication requests.

Master can check if command was executed in “Parameter access status register” – see **table E**.

Supported commands

Command	Command [hex]	Typ. execution time [ms]	Description
'A'	0x41	Set with parameter	Self-calibration start
'b'	0x62	1	Persistent detailed status reset
'c'	0x63	70	Save current configuration to non-volatile memory
'r'	0x72	70	Configuration reset to factory defaults

Position offset (encoder zero position)

Position offset value is substracted from the raw encoder position. Position offset is mapped to the registers 0x00 - 0x03 of bank 3 in a big-endian format. User must write separate bytes of a new position offset in counts to these addresses. Afterwards, they can be read to verify the proper write operation. If the absolute applied position offset is greater than the actual encoder resolution, value will not get updated.

Position offset will be applied only on absolute communicational channel. Position offset does not have impact on ABZ.

In case of position counting direction change, position offset has to be updated (write position offset 0, read current position and write it to position offset).

To store new value into non-volatile memory use the following sequence:
KEY: write value 0xCD to address 0x48.
Command for saving programmed data to a non-volatile memory: write value 0x63 to address 0x49.

Saving the parameters in the non-volatile memory takes 70 ms. During this time, the encoder position is not calculated.

Self-calibration

Self-calibration of Artos is suitable after mounting the readhead. It improves the accuracy of the encoder, which depends on the mounting precision. It can be triggered by sending the KEY (0xCD) to the Key register (address 0x48) and afterwards sending the Self-calibration start command (0x41) to the Command register (address 0x49). No communication via the BiSS interface is possible during the process; the encoder does not respond to incoming clock cycles. The completion of the process is indicated by the LED flashing rapidly for 3 seconds. If the self-calibration was successful, the LED flashes green, otherwise it flashes red. The BiSS interface is then active again. The status of self-calibration can be read from a register 0x00 in bank 4. It consists of a two-bit counter. The counter is incremented at the end of each self-calibration. Status bits indicate success or reasons for failure.

Prior to the self-calibration process, the status should be read from register 0x00 - 0x03 in bank 4. The controller must remember the current self-calibration counter (bits 1:0). After sending the self-calibration command, LED must be observed for completion. If the LED is not visible, the readhead should be polled via the BiSS interface until communication with the readhead is re-established, or wait 10 seconds, which is the default timeout for completion. The self-calibration status register should then be read out again. When the self-calibration counter has increased by 1 (compared to the previously read value), the self-calibration function has been completed. Additional data from the self-calibration is available in bank 4 and includes the measurement of the ring eccentricity and the placement of the readhead.

Speed and direction of rotation during self-calibration are not important and may be inconsistent. The only requirement is that the shaft makes at least one complete revolution within 10 seconds of the command being sent. If the default setting of 10 seconds is not sufficient, this period can be extended to up to 40 seconds using register 0x0C, bank 4.

Address	Type	Range	Units	Meaning / usage
INPUT				
0x0C, bank 4	U8	1 – 40	s	Calibration timeout
0x48	U8	0xCD	-	Key
0x49	U8	0x41	-	Command
OUTPUT, bank 4				
0x06 - 0x07	U16	-	µm	Ring eccentricity shift from rotation axis centre
0x08 - 0x09	U16	0 – 360	degrees	Ring eccentricity angle (phase)
0x0A - 0x0B	S16	-	µm	Average readhead radial shift (distance to nominal ride height: Actual RH [µm] = nominal RH – radial shift) [µm]
0x00 - 0x03	U32	-	bit	Status - see table below

Self-calibration status register:

Bit	Meaning
b21	Error - Parameters could not be saved to non-volatile memory (system fault).
b20	Indication - Error map table is not default (self-calibration was successfully performed). Comparison is executed at power-up and at every command “Save current configuration to non-volatile memory”.
b19	Reserved
b18	Reserved
b17	Reserved
b16	Reserved
b15	Reserved
b14	Indication - Eccentricity is already low (no correction is needed).
b13	Error - Eccentricity is very high.

b12	Error - Numerical error during data processing.
b11	Reserved
b10	Reserved
b9	Error - Encoder is in error state while calibration is started - aborted.
b8	Timeout - Encoder did not complete full revolution (or partial arc) in preset time.
b7	Reserved
b6	Error
b5	Ring positioning is already perfect - correction was not performed.
b4	Confirmation - Self calibration successfully completed.
b3	Reserved
b2	Reserved
b1:b0	Counter is incremented at the end of self-calibration procedure.

When self-calibration is completed without error, the new parameters are automatically stored in non-volatile memory and no further command is required. All numeric results from the calibration are stored in the volatile memory and are cleared on the power cycle. To verify if encoder was already calibrated, read the Self-calibration status register and verify that bit b6 (0x40) is set.

Velocity filter

Internally calculated velocity (rotational speed) is passed through the low-pass filter. This gives smoother position value on communication interface. Increased Value parameter increases filter strength and reduces cut-off frequency. Filter is constant and not dependent on the rotational speed.

Address	Name	Default	Range	Description
0x0C – 0x0F	Velocity filter value	190	0 – 240	Value of Velocity Filter. 0 = filter disabled

Filter settings

Settings are present in bank 3 - Encoder configuration bank.

Changing filter values may cause encoder or closed control loop to become unstable. Use with caution and evaluate all possible situations before keeping the new values.

Saving configuration parameters

Sending a programming command byte 'c' triggers the procedure to save all configuration parameters of the encoder in the non-volatile memory. These parameters also include the position offset.

KEY: write value 0xCD to address 0x48.
Command for saving programmed data to a non-volatile memory: write value 0x63 to address 0x49.

Saving the parameters in the non-volatile memory takes 70 ms. During this time, the encoder position is not calculated.

Reset to factory defaults

Resetting to the factory defaults will set all programmed parameters to the default values. This includes the zero position, the calibration results and others.

KEY: write value 0xCD to address 0x48.
Command for saving programmed data to a non-volatile memory: write value 0x72 to address 0x49.

Saving the parameters in the non-volatile memory takes 70 ms. During this time, the encoder position is not calculated.

After locking the write access, the encoder cannot be reset to the factory defaults.

Write protection

Write protection can be used to lock the write access of any writable register in Artos memory map, except of Bank select register. It is mapped to the register 0x3E of bank 3. Its default value is 0x5A. To lock the write access, user should write any value other than 0x5A. After that, the write access of any register, except of Bank select, will be refused.
All registers will behave as a non writable registers.

KEY: write value 0xCD to address 0x48.
Command for saving programmed data to a non-volatile memory: write value 0x63 to address 0x49.

Saving the parameters in the non-volatile memory takes 70 ms. During this time, the encoder position is not calculated.

After locking the write access, the readhead cannot be programmed anymore. All registers are still readable.
